BACKGROUND
The leucine-rich (LRR) repeat is a 20-30 amino acid motif that forms a hydrophobic α/β horseshoe fold, allowing it to accommodate several leucine residues within a tightly packed core. All LRR repeats contain a variable segment and a highly conserved segment, the latter of which accounts for 11 or 12 residues of the entire LRR motif. LRRs are present in many proteins from prokaryotes to eukaryotes. DSPG3 (dermatan sulfate proteoglycan 3), also known as PGLB, Pg-Lb, SLRR3B or EPYC, is a 322 amino acid secreted protein that belongs to the small leucine-rich proteoglycan (SLRP) family. Expressed in cartilage, ligament and placenta, DSPG3 may have a role in bone formation and in establishing the ordered structure of cartilage through matrix organization. It has been suggested that DSPG3 regulates fibrillogenesis by interacting with collagen fibrils and other extracellular matrix proteins.
