

ISG20L2 (K-15): sc-164707

BACKGROUND

ISG20L2 (interferon-stimulated 20 kDa exonuclease-like 2), also known as HSD38, is a 353 amino acid nuclear protein that contains one exonuclease domain. ISG20L2 acts as an exoribonuclease involved in ribosome biogenesis and exhibits a strong specificity for free hydroxyl groups present on the 3' end of rRNA. Exhibiting 3' to 5' exoribonuclease activity, ISG20L2 is involved in the biogenesis of large ribosomal subunits via the processing of the 12 S precursor rRNA. The gene encoding ISG20L2 maps to human chromosome 1q23.1 and mouse chromosome 3 F1. Human chromosome 1 spans 260 million base pairs, contains over 3,000 genes, comprises nearly 8% of the human genome and houses a large number of disease-associated genes, including those that are involved in familial adenomatous polyposis, Stickler syndrome, Parkinson's disease, Gaucher disease, schizophrenia and Usher syndrome.
