IL-17 (G-4): sc-374218

BACKGROUND

Cytokines are small, soluble proteins with pleiotropic effects on a variety of cell types. Cytokines have a regulatory function over the immune system and mediate aspects of inflammatory response. They exert their biological effects through the binding of membrane-bound receptors which, in turn, initiate signal transduction cascades and elicit physiological changes in their target cell. Interleukin-17 (IL-17) and its cognate receptor, IL-17R, are an example of such a cytokine receptor pair. Originally identified as a rodent cDNA termed CTLAB, IL-17 is capable of inducing the secretion of IL-6 and IL-8 and augmenting the expression of ICAM-1 in human fibroblast cultures. The IL-17 protein exhibits a striking degree of homology with the HSV13 protein which mimics its function. The IL-17 receptor is a type I transmembrane protein consisting of four extracellular domains and a single transmembrane domain, each composed of seven potential transmembrane α helices. IL-17 is a member of the IL-16 superfamily and has pleiotropic effects on various cell types. It stimulates the expression of pro-inflammatory cytokines, chemokines, and adhesion molecules, and promotes the proliferation and survival of certain cell types.
