**BACKGROUND**

Nop132, also known as NOL8 (nucleolar protein 8), is a 1,167 amino acid nuclear protein that contains one RRM (RNA recognition motif) domain and exists as 4 alternatively spliced isoforms. While playing an essential role in the survival of diffuse-type gastric cancer cells, Nop132 may also be involved in the regulation of post-transcriptional gene expression and ribosome biogenesis of cancer cells. Although it is expressed at low levels in skeletal muscle, Nop132 is upregulated in diffuse-type gastric cancers. Nop132 interacts with NIP7, as well as the GTP form of Rag A/B, Rag C and Rag D. The gene that encodes Nop132 consists of approximately 28,237 bases and maps to human chromosome 9q22.31. Housing over 900 genes, chromosome 9 comprises nearly 4% of the human genome. Hereditary hemorrhagic telangiectasia, which is characterized by harmful vascular defects, and Familial dysautonomia, are both associated with chromosome 9. Notably, chromosome 9 encompasses the largest interferon family gene cluster.
