**BACKGROUND**

The majority of mitochondrial-directed proteins are encoded by the nuclear genome and are transported to the mitochondria via regulated processes involving the mitochondrial Tom and Tim proteins. The mitochondrial Tim protein family is comprised of a large group of evolutionarily conserved proteins that are found in most eukaryotes. Import of nuclear-encoded precursor proteins into and across the mitochondrial inner membrane is mediated by two distinct complexes, the Tim23 complex and the Tim22 complex, which differ in their substrate specificities. Defects in Tim proteins are implicated in several neuro-degenerative diseases, suggesting important roles for Tim proteins in development and health.

Tim50, also known as Tim50 Lor TIMM50, is ubiquitously expressed and functions as an important component of the Tim23 complex. Two isoforms of Tim50 are produced by alternative splicing. Isoform 1 localizes to the inner mitochondrial membrane, whereas isoform 2 localizes to nuclear speckles.
