**BACKGROUND**

Muscle contraction is activated by the release of calcium from the sarcoplasmic reticulum (SR), and muscle relaxation is triggered by a rapid re-uptake of calcium from the cytosol into the lumen of the SR. Sarcalumenin is a glycoprotein expressed in the longitudinal tubules in the lumen of the sarcoplasmic reticulum (SR) in striated muscle cells, and it associates with the inner side of the SR membranes through calcium bridges. Endogenous casein kinase II may regulate its function via phosphorylation of Sarcalumenin. Sarcalumenin binds to calcium and helps to sequester it in the nonjunctional regions of the sarcoplasmic reticulum. Sarcalumenin also improves upon the condition of calcium pump proteins. Basic mammalian muscle functions do not require a functional Sarcalumenin, but loss of this protein causes slowed contraction and relaxation.
